

# Harden Savanna of MRCP

Baseline vegetation survey with photos

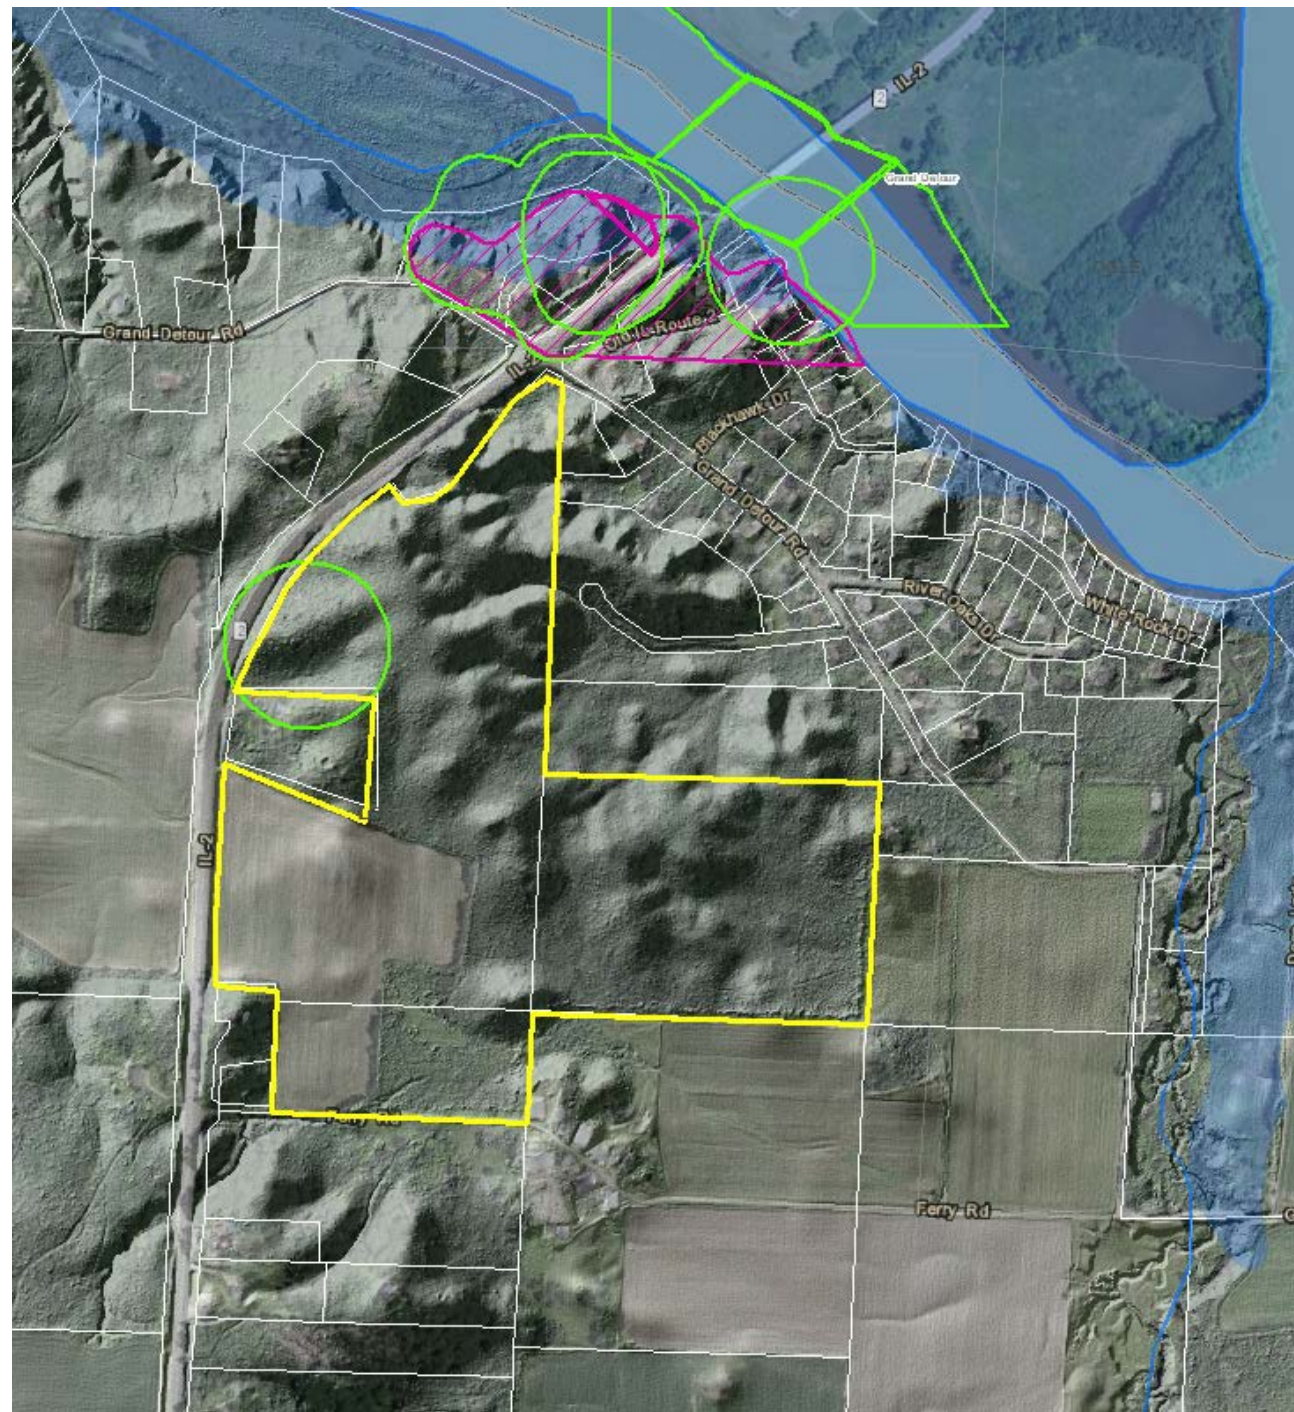

August 2019

Coordinated by Bill Kleiman, TNC

Team included Elizabeth Bach, Jenn Simons, Mike Jones

We met our goal to gather baseline vegetation data and photos so that ten years from now we can demonstrate the results of our good stewardship.

# Harden Topography via lidar

**1939 Harden Savanna**

**Current**

# Current Harden Savanna

# 1939 Harden Savanna

# 1939 Harden Savanna

- Before old world settlement the land was likely Native American hunting and camping with high ground above a major river.
- By 1939 the tract was likely a prairie and oak savanna with livestock grazing.
- 80 years go by and the brush and trees fill in.
- Shade is hard on savannas
- We have work to do.
- To restore good oak savanna habitat with a diverse herbaceous and shrub layer would be an uncommon success.

# Random points were generated and numbered

A closeup  
of some  
of the  
random  
points.

The data  
and  
photos  
correspon  
d to these  
numbers.

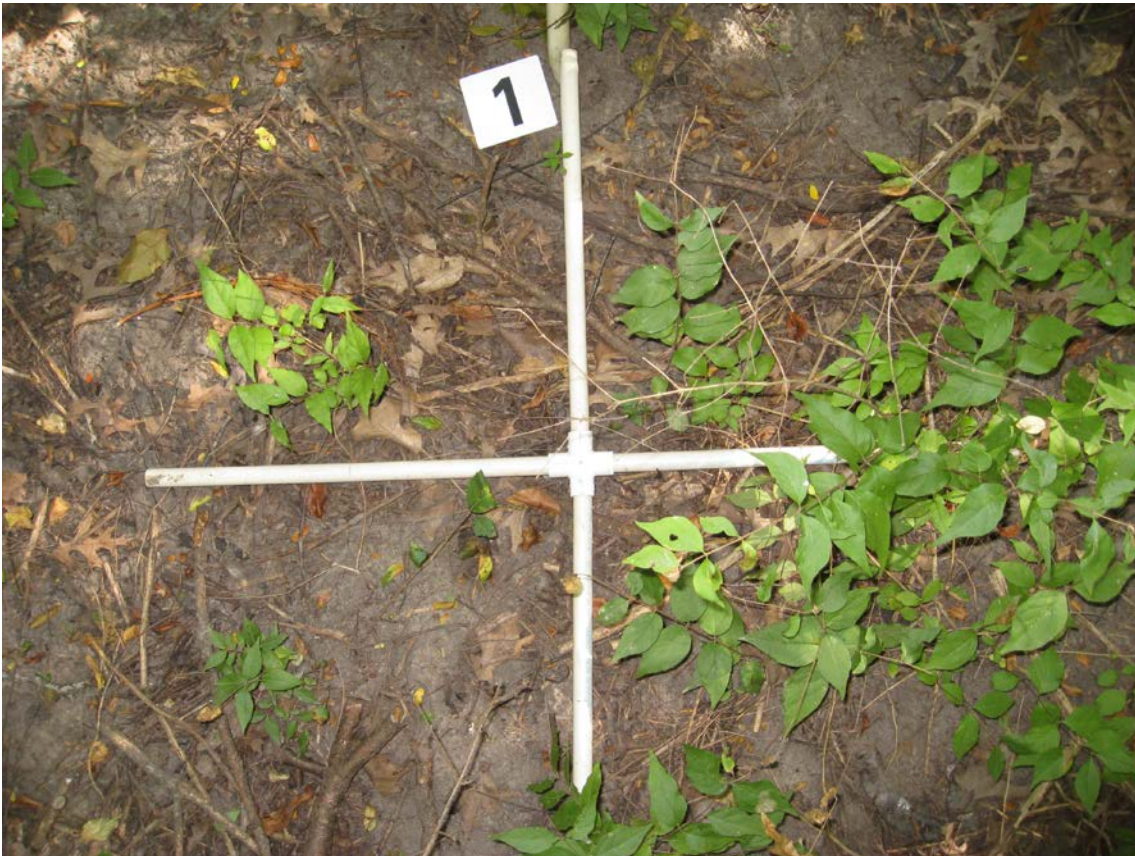

# Where we sampled

- We only sampled one community type, the currently closed canopy.
- This was due to time and fund restraints.
- We chose not to sample the Department of Transportation lands. The old vegetation surveys done decades back by DOT are likely available to use as our baseline.

All plant species in the meter by meter quadrat were recorded as percent cover.

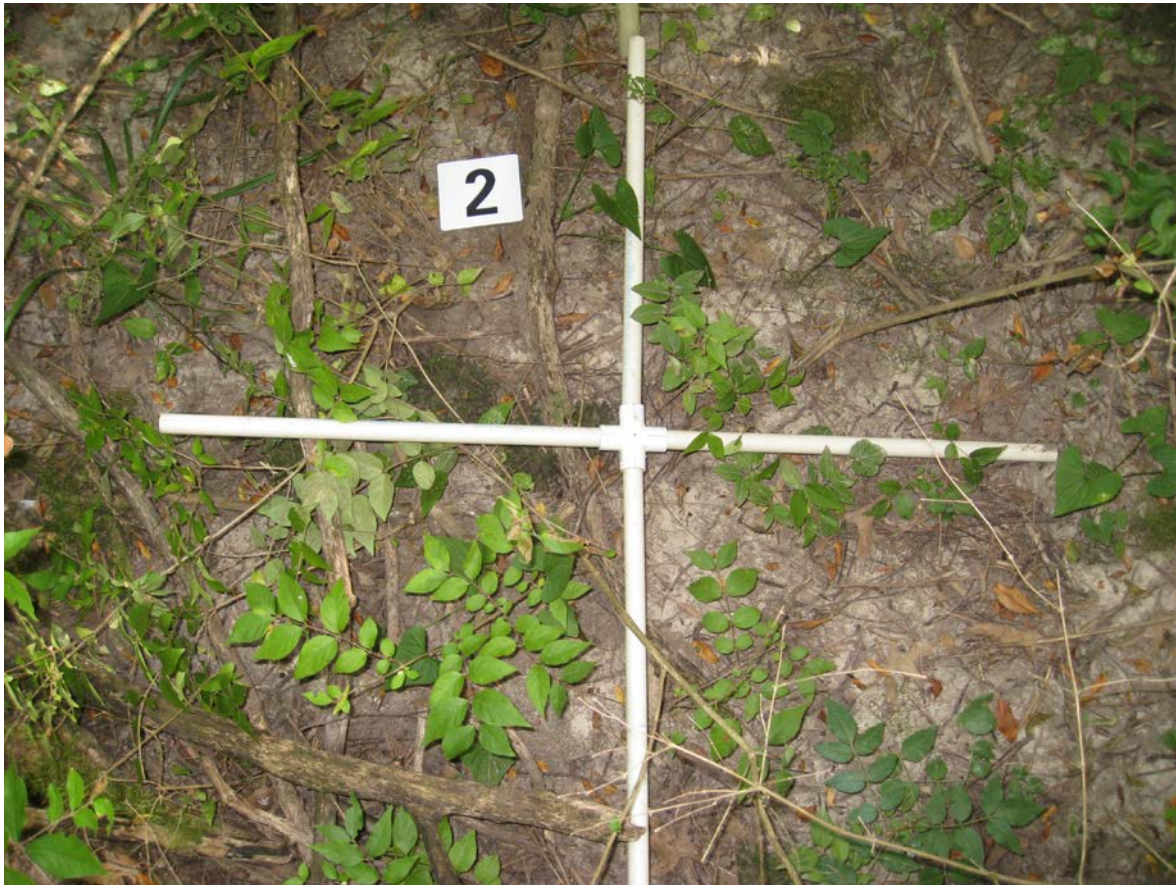

**We took a photo of each quadrat looking down**

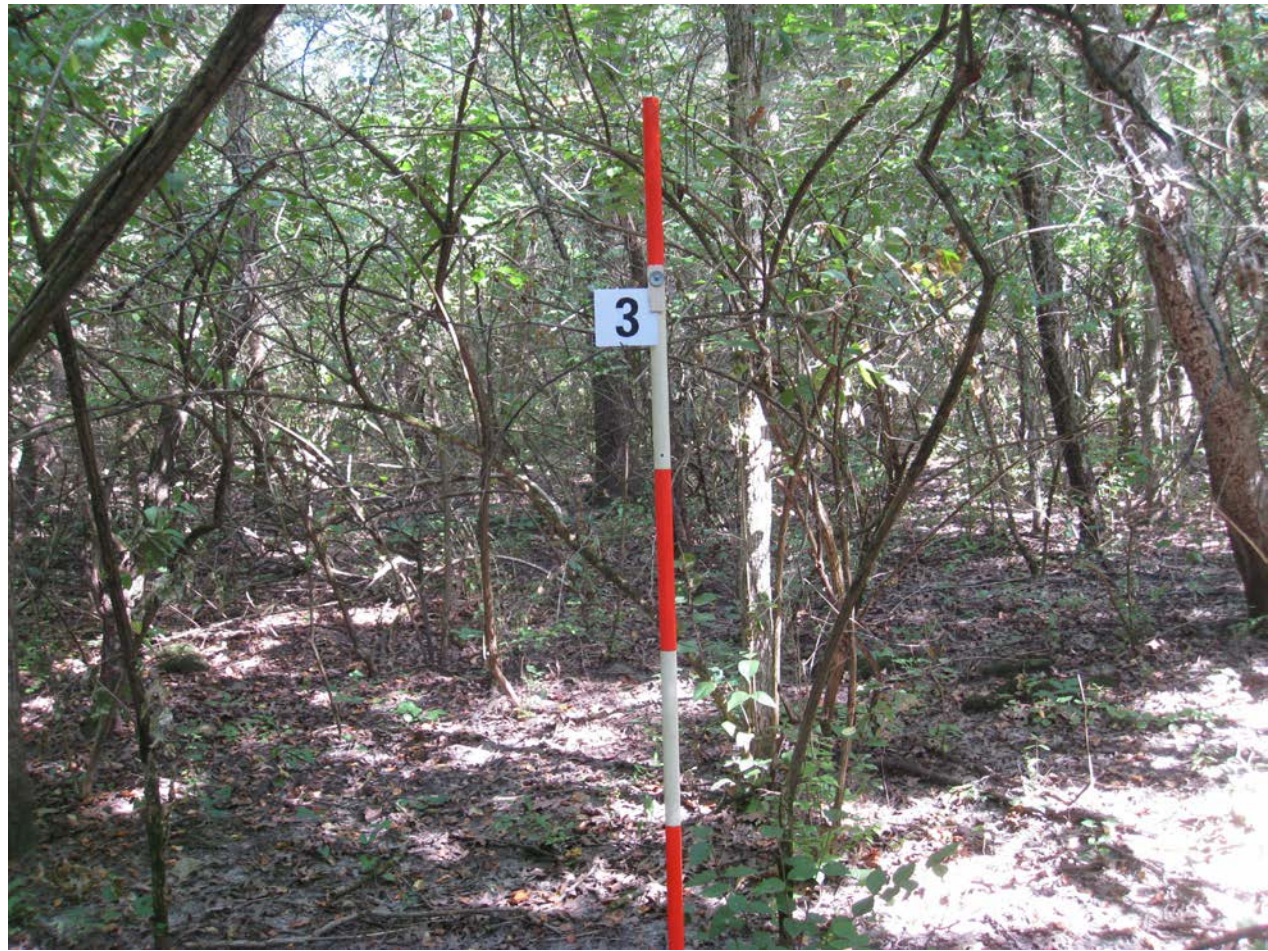

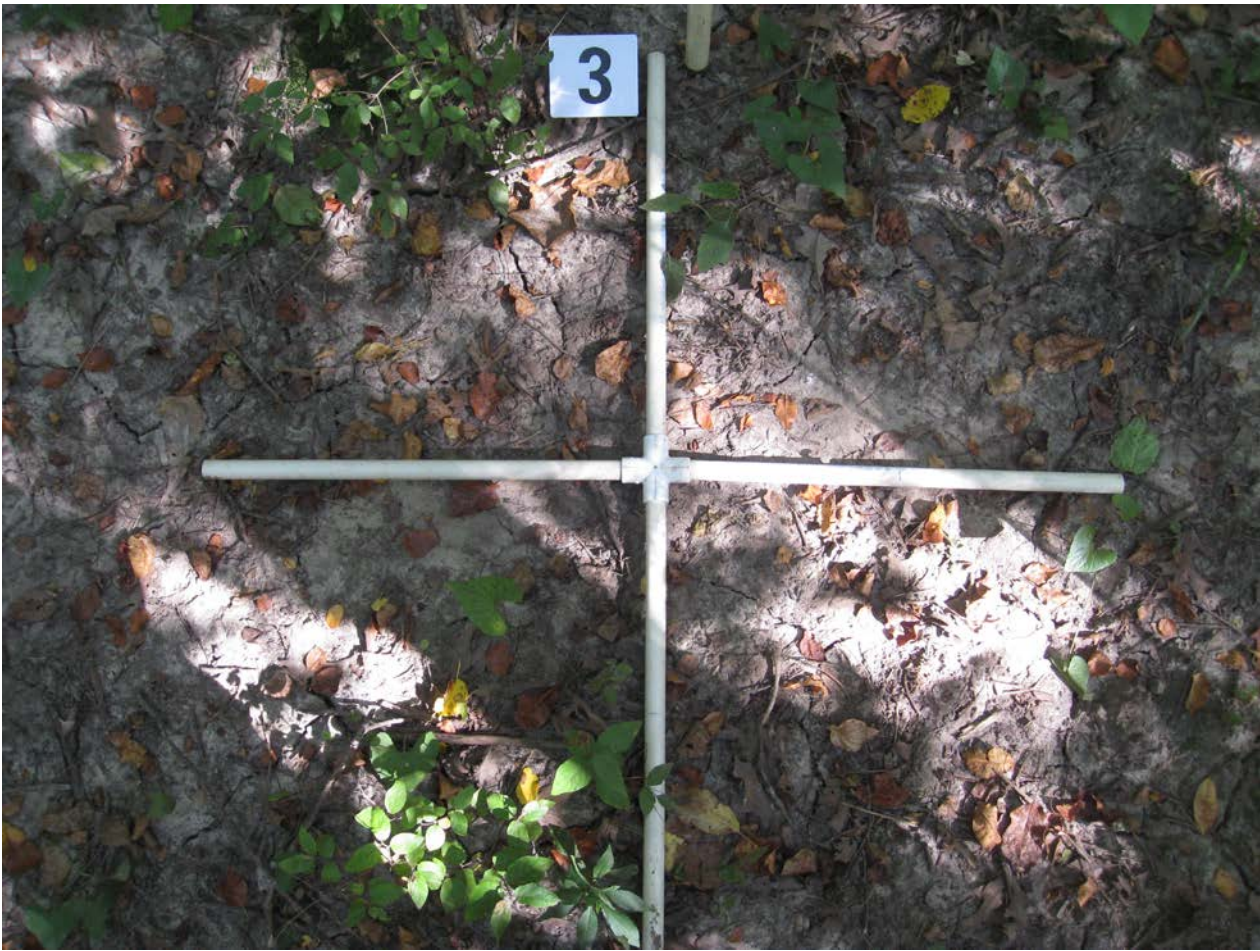

**And a photo looking north**

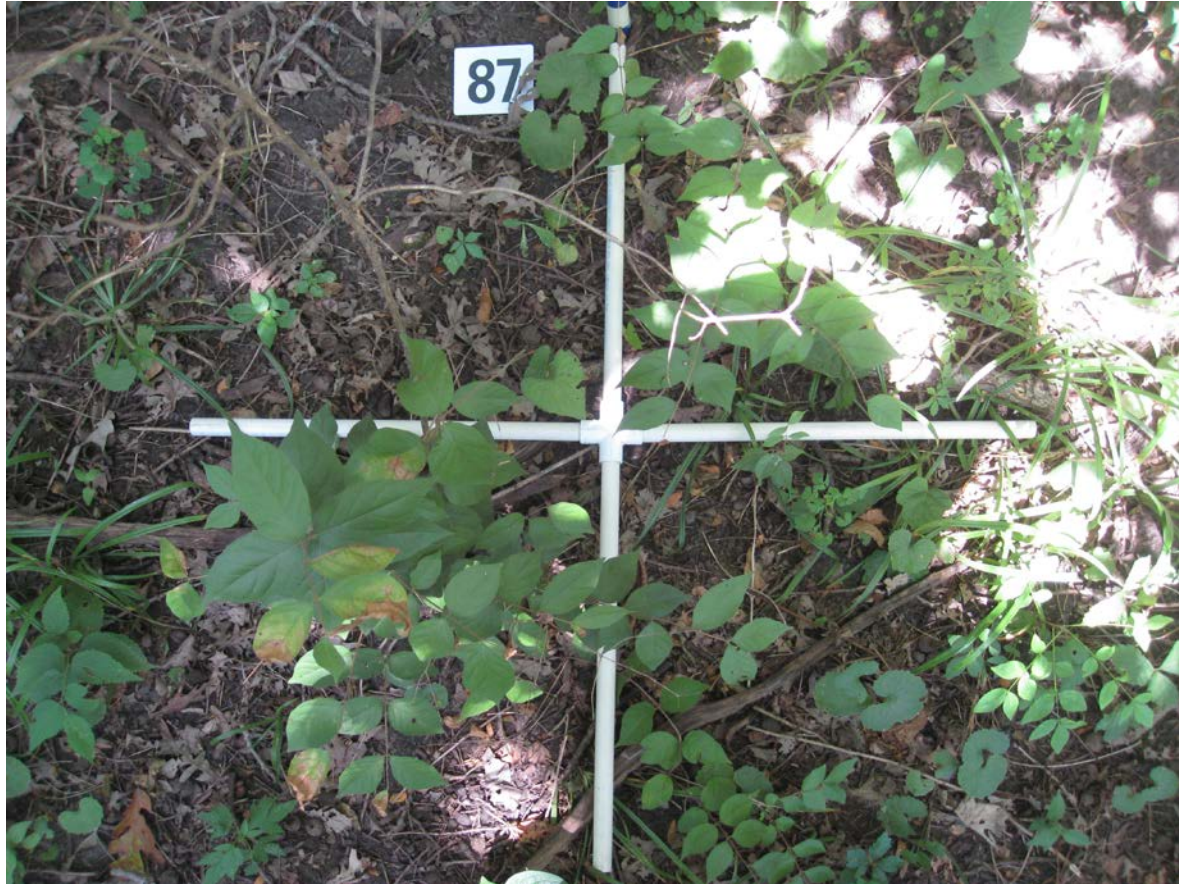

# Quadrat 2 showing typical extensive bare soil

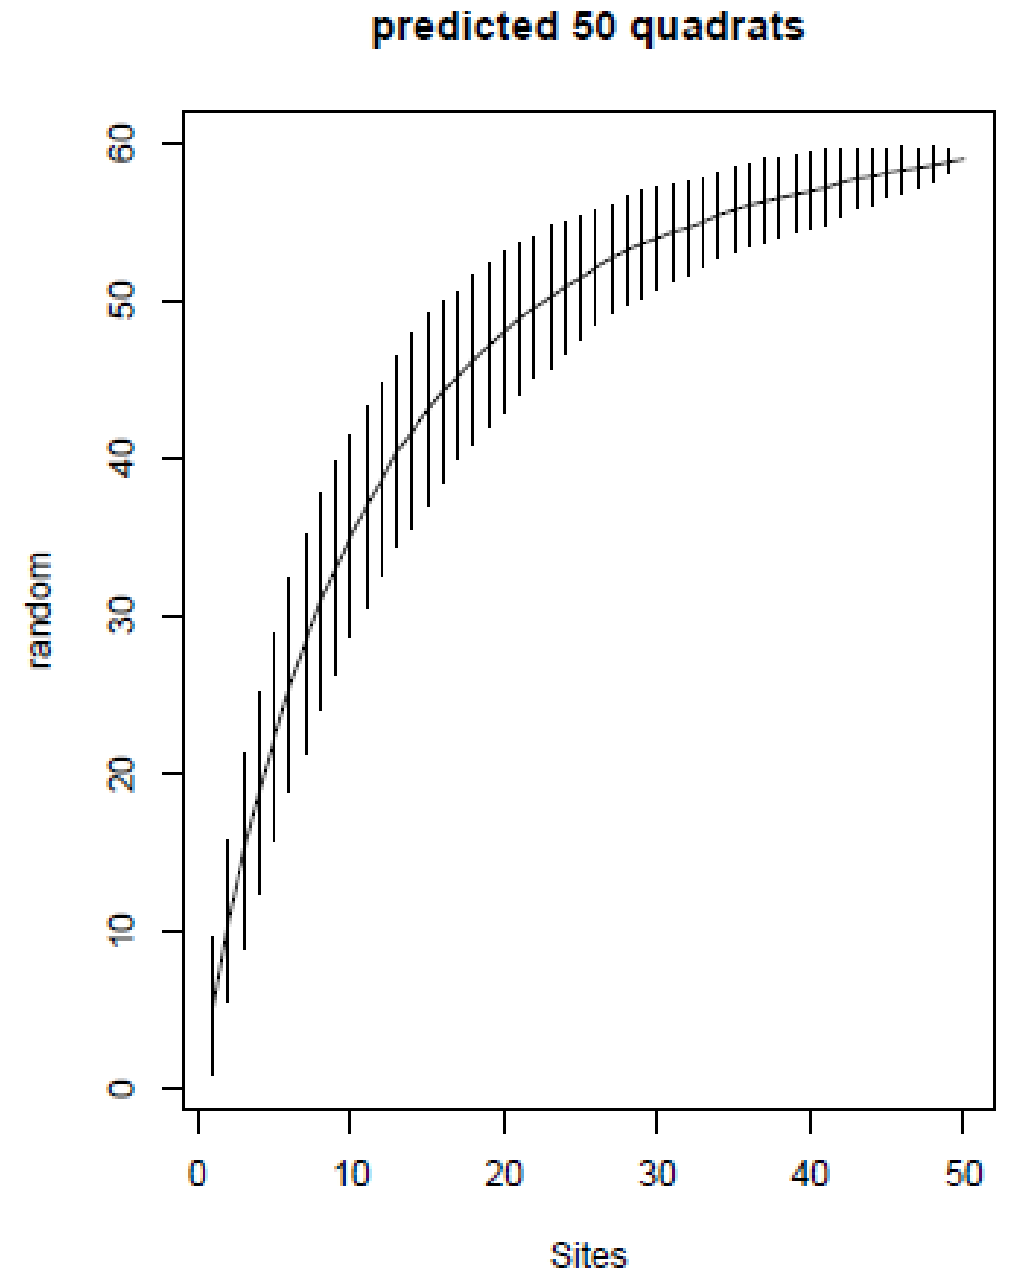

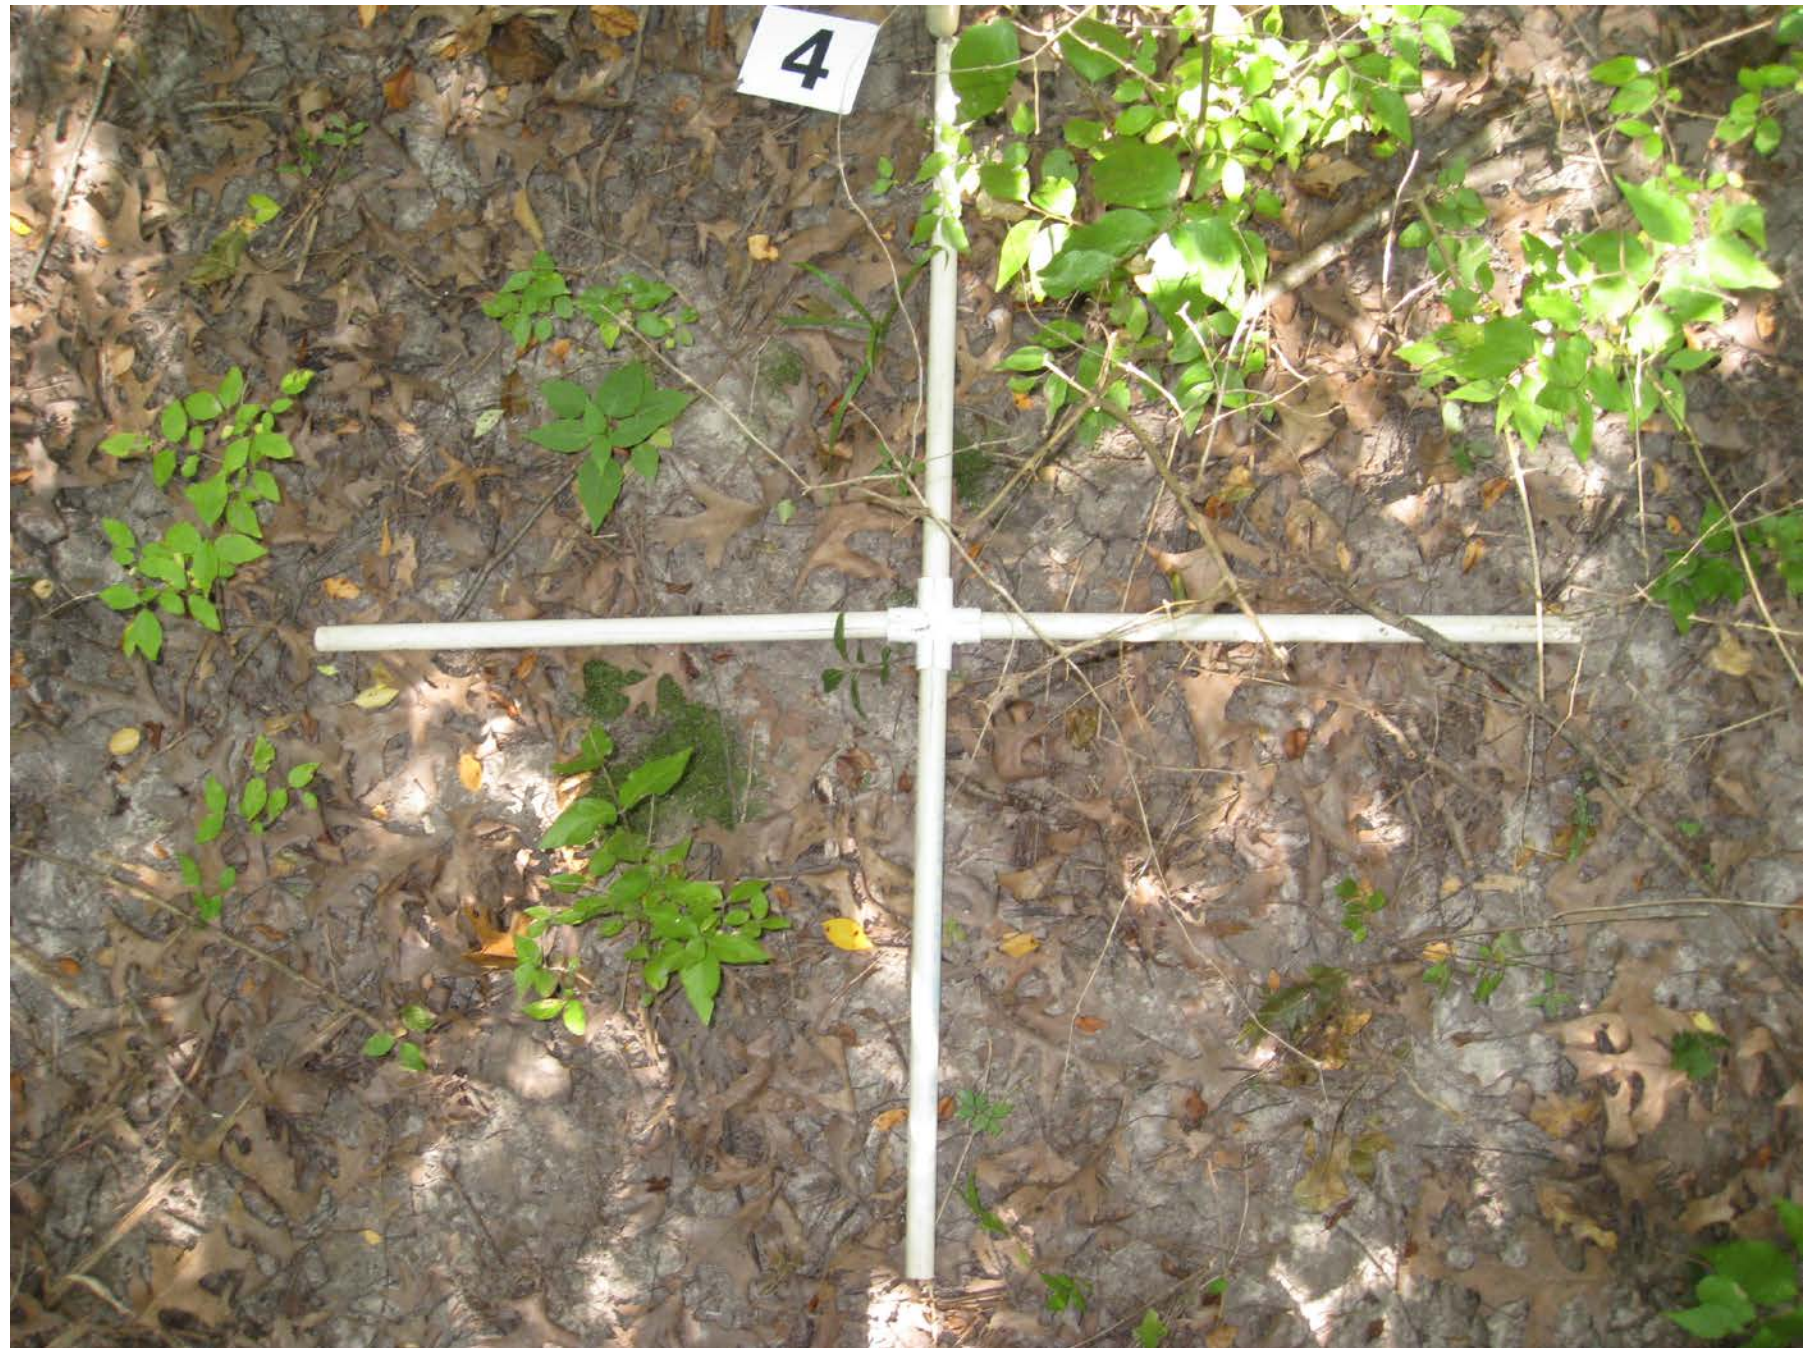

After the first day of 24 quadrats of sampling Elizabeth analyzed that data which predicted 50 quadrats would be enough to have confidence we sampled enough places. This is the species accumulation curve.

Close up  
of quadrat  
4.  
5 species  
in this  
quadrat,  
but mostly  
exposed  
soil.

Close up  
photo  
looking  
north from  
quadrat 4.

The three  
closest trees  
to each  
quadrat  
were noted.

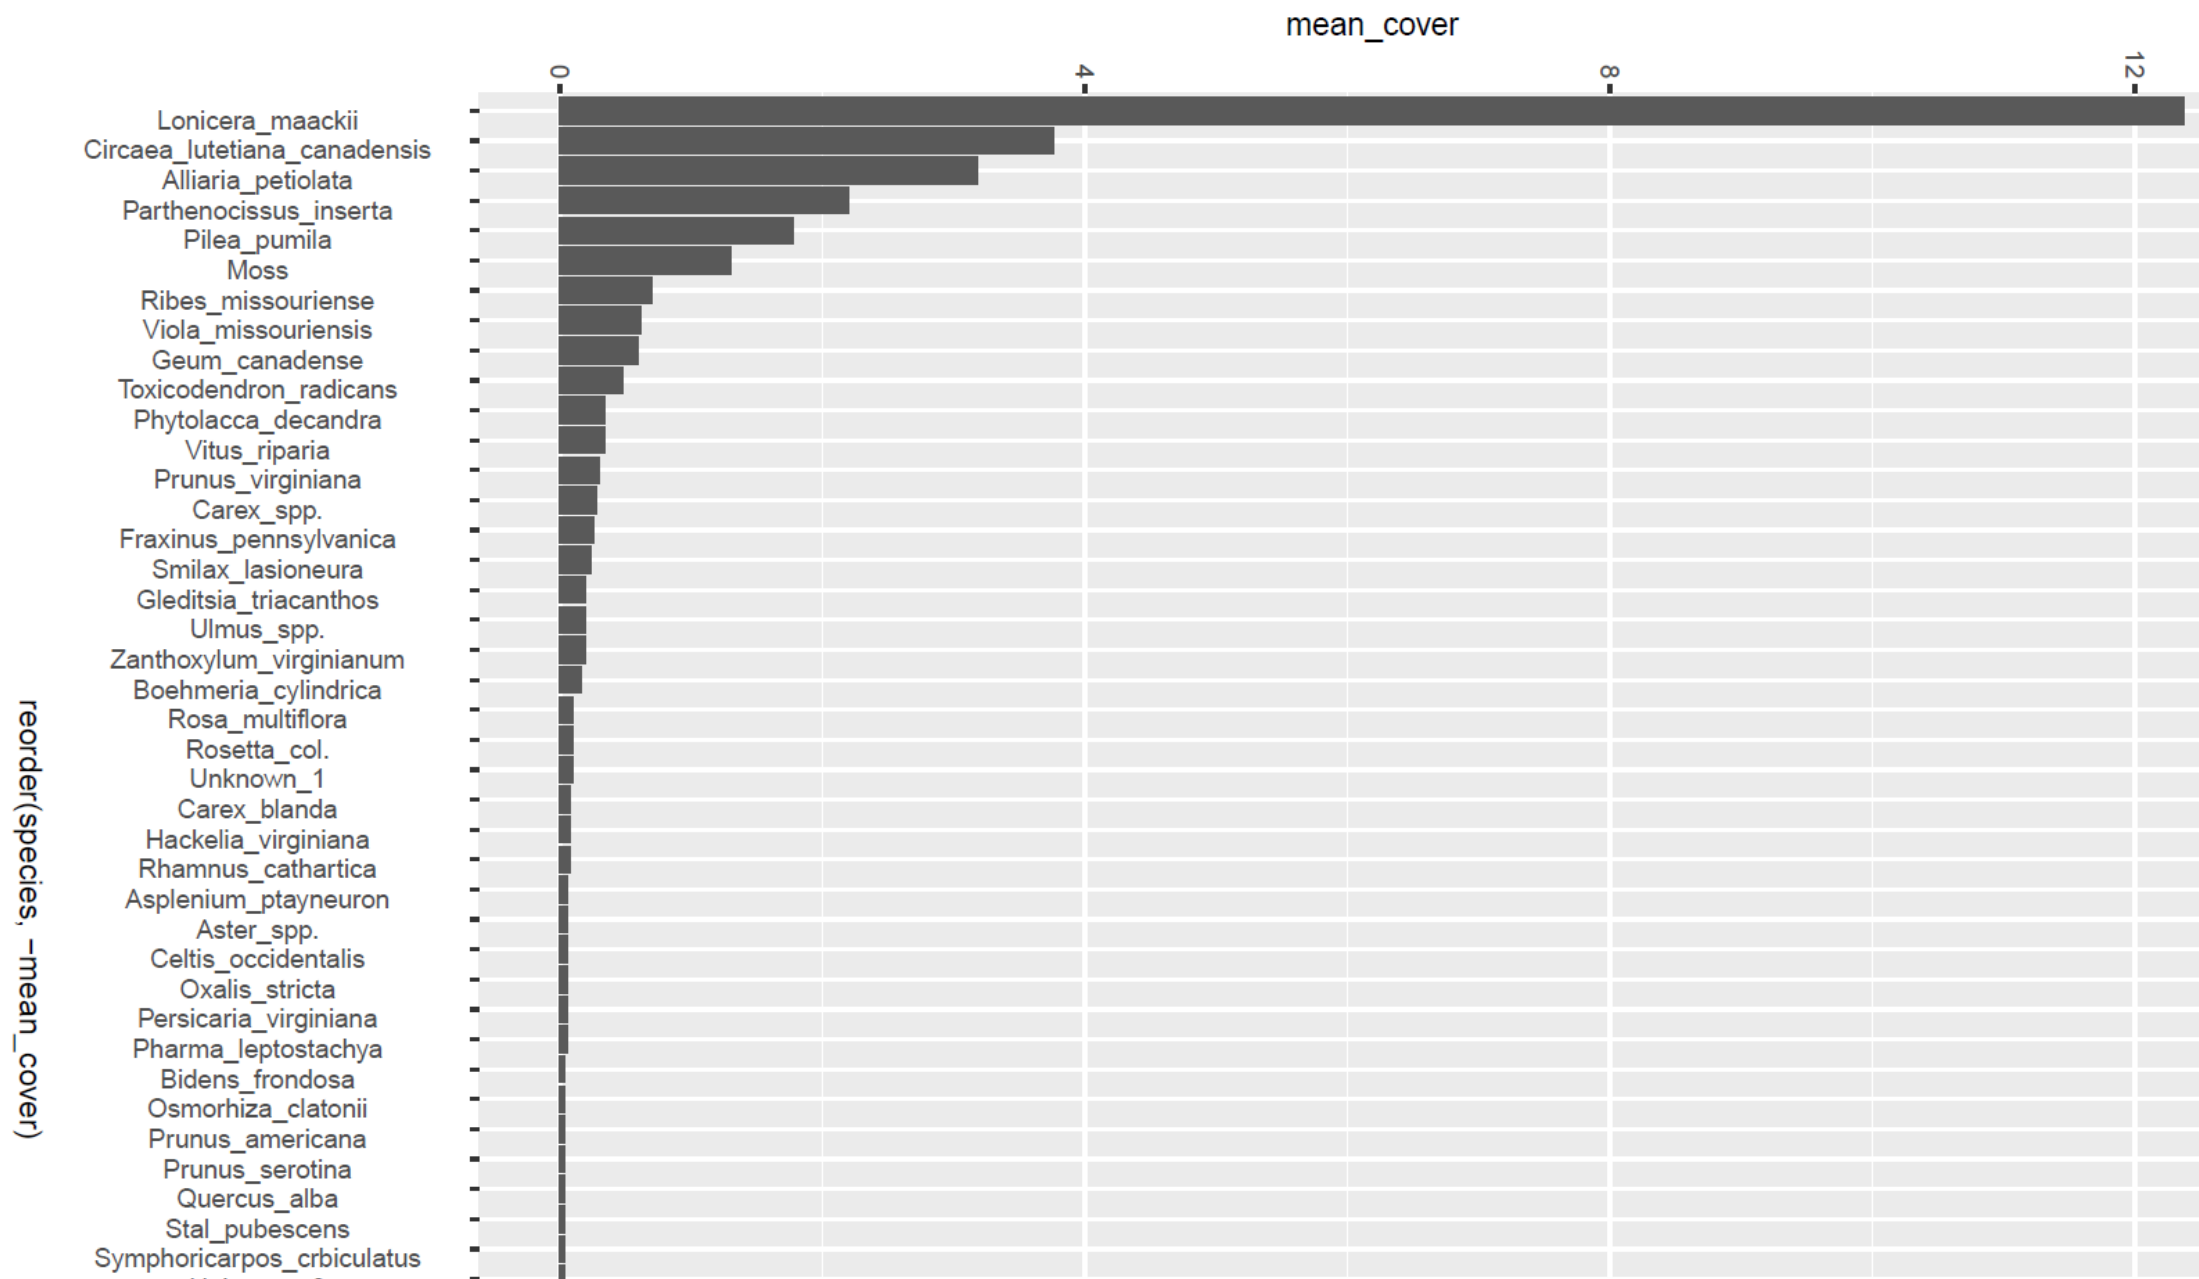

The vegetation team were L to R: Mike Jones, our hired botanist; Elizabeth Bach, Nachusa Scientist; Jenn Simons, Nachusa science intern; Bill Kleiman, Nachusa director. Bill came up with the protocol. Elizabeth helped refine the protocol and do statistics. Mike was the field botanist. Jenn took photos, recorded data and did data entry.

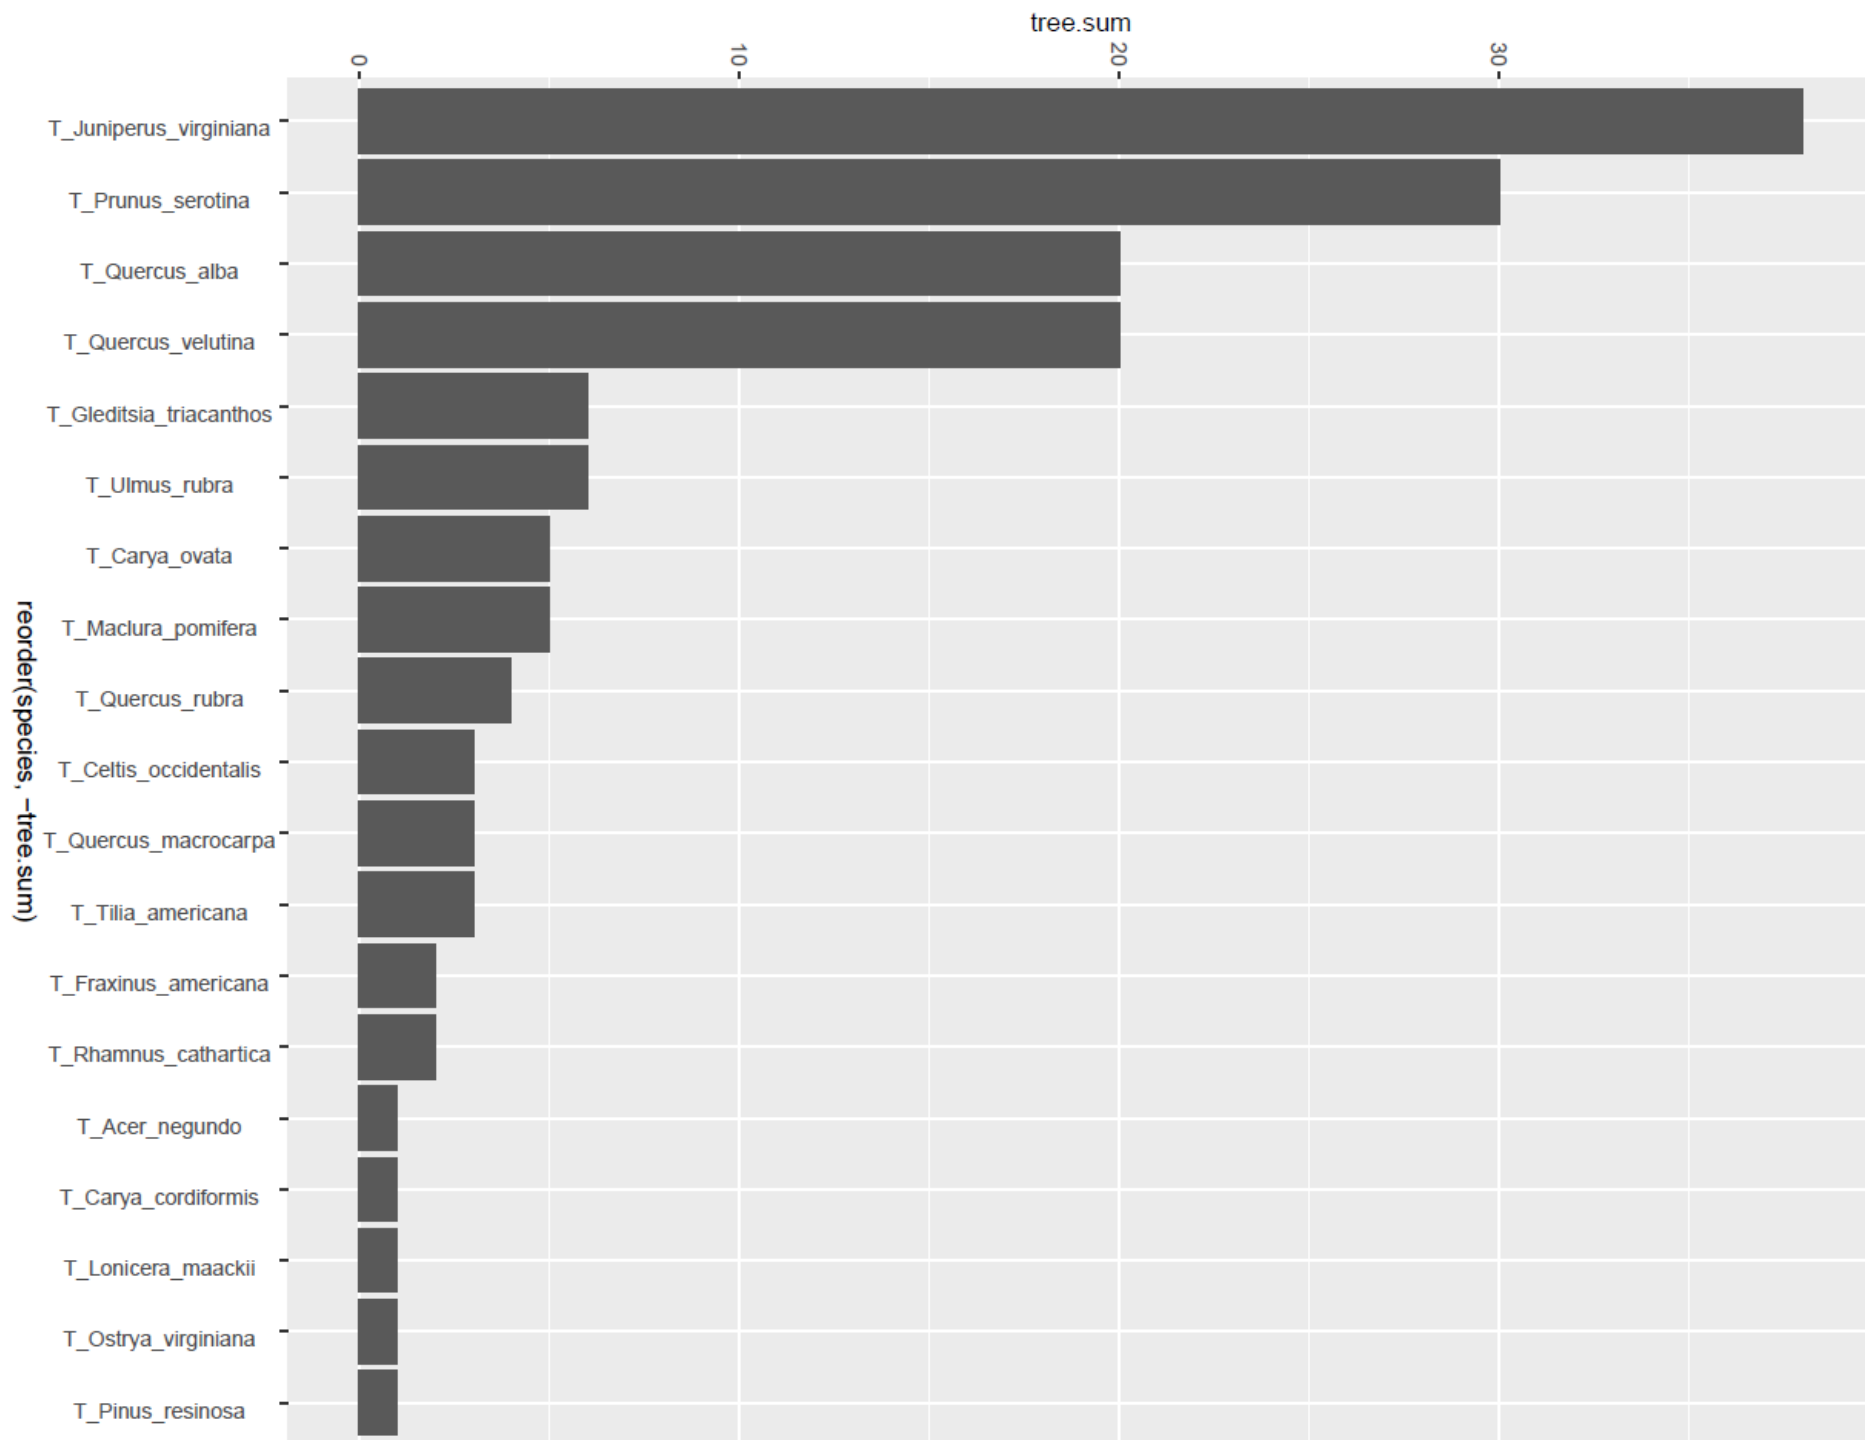

# Summary of data for Harden Savanna

- 75% of the quadrats were bare soil.
- The most common plant was invasive honeysuckle, *Lonicera maackii*.
- The top ten most common species were all exotics or weedy natives.  
In order: honeysuckle, enchanters nightshade, garlic mustard, Virginia creeper, clearweed, moss, gooseberry, Missouri violet, white avens, poison ivy.
- There were 55 plant species but their presence was insignificant.

We also noted the 3 trees closest to each quadrat.  
Tree being anything 5cm diameter or larger

- The most common tree was eastern red cedar. Cedar would have begun growth in the open savanna and are now barely holding on in dense shade.
- Black cherry was the second most encountered tree.
- White oak and black oak were still commonly encountered.
- The remaining trees were encountered infrequently.
- 19 tree species in total.

# A list of stewardship we can do to return land health to the Harden tract includes:

- Define boundaries
- Use a forestry mower to create fire breaks
- Forestry mow interior areas
- Use prescribed fire as frequently as possible
- Basal bark herbicide the brush
- Seed areas as soon as they are cleared of some brush
- Repeat

Data and photos are stored at Nachusa and on MRCP Box account

MRCP cost was \$400. The remainder was TNC  
Nachusa staff time.

End
